Bilinear Factor Matrix Norm Minimization for Robust PCA: Algorithms and Applications

Fanhua Shang, Member, IEEE, James Cheng, Yuanyuan Liu, Zhi-Quan Luo, Fellow, IEEE, and Zhouchen Lin, Senior Member, IEEE

Abstract—The heavy-tailed distributions of corrupted outliers and singular values of all channels in low-level vision have proven effective priors for many applications such as background modeling, photometric stereo and image alignment. And they can be well modeled by a hyper-Laplacian. However, the use of such distributions generally leads to challenging non-convex, non-smooth and non-Lipschitz problems, and makes existing algorithms very slow for large-scale applications. Together with the analytic solutions to $\ell_1$-norm minimization with two specific values of $p$, i.e., $p = 1/2$ and $p = 2/3$, we propose two novel bilinear factor matrix norm minimization models for robust principal component analysis. We first define the double nuclear norm and Frobenius/nuclear hybrid norm penalties, and then prove that they are in essence the Schatten-$1/2$ and $2/3$ quasi-norms, respectively, which lead to much more tractable and scalable Lipschitz optimization problems. Our experimental analysis shows that both our methods yield more accurate solutions than original Schatten quasi-norm minimization, even when the number of observations is very limited. Finally, we apply our penalties to various low-level vision problems, e.g., text removal, moving object detection, image alignment and inpainting, and show that our methods usually outperform the state-of-the-art methods.

Index Terms—Robust principal component analysis, rank minimization, Schatten-$p$ quasi-norm, $\ell_p$-norm, double nuclear norm penalty, Frobenius/nuclear norm penalty, alternating direction method of multipliers (ADMM)

1 INTRODUCTION

The sparse and low-rank priors have been widely used in many real-world applications in computer vision and pattern recognition, such as image restoration [1], face recognition [2], subspace clustering [3], [4], [5] and robust principal component analysis [6] (RPCA, also called low-rank and sparse matrix decomposition in [7], [8] or robust matrix completion in [9]). Sparsity plays an important role in various low-level vision tasks. For instance, it has been observed that the gradient of natural scene images can be better modeled with a heavy-tailed distribution such as hyper-Laplacian distributions $p(x) \propto e^{-|x|^\alpha}$, typically with $0.5 \leq \alpha \leq 0.8$, which correspond to non-convex $\ell_\alpha$-norms) [10], [11], as exhibited by the sparse noise/outliers in low-level vision problems [12] shown in Fig. 1. To induce sparsity, a principled way is to use the convex $\ell_1$-norm [6], [13], [14], [15], [16], [17], which is the closest convex relaxation of the sparser $\ell_0$-norm, with compressed sensing being a prominent example. However, it has been shown in [18] that the $\ell_1$-norm over-penalizes large entries of vectors and results in a biased solution. Compared with the $\ell_1$-norm, many non-convex surrogates of the $\ell_q$-norm listed in [19] give a closer approximation, e.g., SCAD [18] and MCP [20]. Although the use of hyper-Laplacian distributions makes the problems non-convex, fortunately an analytic solution can be derived for two specific values of $p$, $1/2$ and $2/3$, by finding the roots of a cubic and quartic polynomial, respectively [10], [21], [22]. The resulting algorithm can be several orders of magnitude faster than existing algorithms [10].

As an extension from vectors to matrices, the low-rank structure is the sparsity of the singular values of a matrix. Rank minimization is a crucial regularizer to induce a low-rank solution. To solve such a problem, the rank function is usually relaxed by its convex envelope [5], [23], [24], [25], [26], [27], [28], [29], the nuclear norm (i.e., the sum of the singular values, also known as the trace norm or Schatten-1 norm [26], [30]). By realizing the intimate relationship between the $\ell_1$-norm and nuclear norm, the latter also over-penalizes large singular values, that is, it may make the solution deviate from the original solution as the $\ell_1$-norm does [19], [31]. Compared with the nuclear norm, the Schatten-$q$ norm for $0 < q < 1$ is equivalent to the $\ell_q$-norm on singular values and makes a closer approximation to the rank function [32], [33]. Nie et al. [31] presented an efficient augmented Lagrange multiplier (ALM) method to solve the joint $\ell_1$-norm and Schatten-$q$ norm (LpSq) minimization. Lai et al. [32] and Lu et al. [33] proposed iteratively reweighted least squares methods for solving Schatten quasi-norm minimization problems. However, all these algorithms have to

be solved iteratively, and involve singular value decomposition (SVD) in each iteration, which occupies the largest computation cost, $O(\min(m,n)mn)$ [34, 35].

It has been shown in [36] that the singular values of non-local matrices in natural images usually exhibit a heavy-tailed distribution ($p(\alpha) \propto e^{-\alpha m^p}$), as well as the similar phenomena in natural scenes [37], [38], as shown in Fig. 2. Similar to the case of heavy-tailed distributions of sparse outliers, the analytic solutions can be derived for the two specific cases of $\alpha$, 1/2 and 2/3. However, such algorithms have high per-iteration complexity $O(\min(m,n)mn)$. Thus, we naturally want to design equivalent, tractable and scalable forms for the two cases of the Schatten-$q$ quasi-norm, $q = 1/2$ and 2/3, which can fit the heavy-tailed distribution of singular values closer than the nuclear norm, as analogous to the superiority of the $\ell_p$ quasi-norm (hyper-Laplacian priors) to the $\ell_1$-norm (Laplacian priors).

We summarize the main contributions of this work as follows. 1) By taking into account the heavy-tailed distributions of both sparse noise/outliers and singular values of matrices, we propose two novel tractable bilinear factor matrix norm minimization models for RPCA, which can fit empirical distributions very well to corrupted data. 2) Different from the definitions in our previous work [34], we define the double nuclear norm and Frobenius/nuclear hybrid norm penalties as tractable low-rank regularizers. Then we prove that they are in essence the Schatten-1/2 and 2/3 quasi-norms, respectively. The solution of the resulting minimization problems only requires SVDs on two much smaller factor matrices as compared with the much larger ones required by existing algorithms. Therefore, our algorithms can reduce the per-iteration complexity from $O(\min(m,n)mn)$ to $O(mnd)$, where $d \ll m, n$ in general. In particular, our penalties are Lipschitz, and more tractable and scalable than original Schatten quasi-norm minimization, which is non-Lipschitz and generally NP-hard [32], [39]. 3) Moreover, we present the convergence property of the proposed algorithms for minimizing our RPCA models and provide their proofs. We also extend our algorithms to solve matrix completion problems, e.g., image inpainting. 4) We empirically study both of our bilinear factor matrix norm minimizations and show that they outperform original Schatten norm minimization, even with only a few observations. Finally, we apply the defined low-rank regularizers to address various low-level vision problems, e.g., text removal, moving object detection, and image alignment and inpainting, and obtain superior results than existing methods.

2 Related Work

In this section, we mainly discuss some recent advances in RPCA, and briefly review some existing work on RPCA and its applications in computer vision (readers may see [6] for a review). RPCA [24], [40] aims to recover a low-rank matrix $L \in \mathbb{R}^{m \times n}$ ($m \geq n$) and a sparse matrix $S \in \mathbb{R}^{m \times n}$ from corrupted observations $D = L^* + S^*$ as follows:

$$\min_{L,S} \lambda \text{rank}(L) + \|S\|_{\ell_0}, \text{ s.t.}, L + S = D,$$

where $\| \cdot \|_{\ell_0}$ denotes the $\ell_0$-norm and $\lambda > 0$ is a regularization parameter. Unfortunately, solving (1) is NP-hard. Thus, we usually use the convex or non-convex surrogates to replace both of the terms in (1), and formulate this problem into the following more general form

$$\min_{L,S} \lambda \|L\|_{\ell_q} + \|S\|_{\ell_p}, \text{ s.t.}, \mathcal{P}_D(L + S) = \mathcal{P}_D(D),$$

where in general $p, q \in [0, 2]$, $\|S\|_{\ell_q}$ and $\|L\|_{\ell_q}$ are depicted in Table 1 and can be seen as the loss term and regularized term, respectively, and $\mathcal{P}_D$ is the orthogonal projection onto the linear subspace of matrices supported on $\Omega := \{(i,j)| D_{ij} \text{ is observed}\}$; $\mathcal{P}_D(D)_{ij} = D_{ij}$ if $(i,j) \in \Omega$ and $\mathcal{P}_D(D)_{ij} = 0$ otherwise. If $\Omega$ is a small subset of the entries of the matrix, (2) is also known as the robust matrix completion problem as in [9], and it is impossible to exactly recover $S^*$ [41]. As analyzed in [42], we can easily see that the optimal solution $S^*_0 = 0$, where $\Omega^*$ is the complement of $\Omega$, i.e., the index set of unobserved entries. When $p = 2$ and $q = 1$, (2) becomes a nuclear norm regularized least squares problem as in [43] (e.g., image inpainting in Section 6.3.4).

2.1 Convex Nuclear Norm Minimization

In [6], [40], [44], both of the non-convex terms in (1) are replaced by their convex envelopes, i.e., the nuclear norm ($q = 1$) and the $\ell_1$-norm ($p = 1$), respectively.

$$\min_{L,S} \lambda \|L\|_1 + \|S\|_{\ell_1}, \text{ s.t.}, L + S = D.$$

Wright et al. [40] and Candès et al. [6] proved that, under some mild conditions, the convex relaxation formulation (3) can exactly recover the low-rank and sparse matrices ($L^*, S^*$) with high probability. The formulation (3) has been widely used in many computer vision applications, such as

1. Strictly speaking, the $\ell_0$-norm is not actually a norm, and is defined as the number of non-zero elements. When $p \geq 1$, $\|S\|_{\ell_p}$ strictly defines a norm which satisfies the three norm conditions, while it defines a quasi-norm when $0 < p < 1$. Due to the relationship between $\|S\|_{\ell_p}$ and $\|L\|_{\ell_q}$, the latter has the same cases as the former.

Let \( \mathbf{U} = (\mathbf{u}_1, \ldots, \mathbf{u}_m) \in \mathbb{R}^{m \times n} \) be the non-zero singular values of \( \mathbf{L} \in \mathbb{R}^{m \times n} \).

object detection and background subtraction [17], image alignment [50], low-rank texture analysis [29], image and video restoration [51], and subspace clustering [27]. This is mainly because the optimal solutions of the sub-problems involving both terms in (3) can be obtained by two well-known proximal operators: the singular value thresholding (SVT) operator [23] and the soft-thresholding operator [52]. The \( \ell_1 \)-norm penalty in (3) can also be replaced by the \( \ell_1,2 \)-norm as in outlier pursuit [28], [53], [54], [55] and subspace learning [5], [56], [57].

To efficiently solve the popular convex problem (3), various first-order optimization algorithms have been proposed, especially the alternating direction method of multipliers [58] (ADMM, or also called inexact ALM in [44]). However, they all involve computing the SVD of a large matrix of size \( m \times n \) in each iteration, and thus suffer from high computational cost, which severely limits their applicability to large-scale problems [59], as well as existing Schatten-q quasi-norm (0 < q < 1) minimization algorithms such as LpSq [31]. While there have been many efforts towards fast SVD computation such as partial SVD [60], the performance of those methods is still unsatisfactory for many real applications [59], [61].

2.2 Non-Convex Formulations

To address this issue, Shen et al. [47] efficiently solved the RPCA problem by factorizing the low-rank component into two smaller factor matrices, i.e., \( \mathbf{L} = \mathbf{U} \mathbf{V}^T \) as in [62], where \( \mathbf{U} \in \mathbb{R}^{m \times d} \), \( \mathbf{V} \in \mathbb{R}^{n \times d} \) and usually \( d \ll \min(m, n) \), as well as the matrix tri-factorization (MTF) [48] and factorized

</table>

Note that \( \mathbf{U} \in \mathbb{R}^{m \times d} \) and \( \mathbf{V} \in \mathbb{R}^{n \times d} \) are the factor matrices of \( \mathbf{L} \), i.e., \( \mathbf{L} = \mathbf{U} \mathbf{V}^T \).
because it is generally non-convex, non-smooth, and non-Lipschitz, as well as the $\ell_q$ quasi-norm [39].

As in some collaborative filtering applications [26], [67], the nuclear norm has the following alternative non-convex formulations.

**Lemma 1.** For any matrix $X \in \mathbb{R}^{m \times n}$ of rank at most $r \leq d$, the following equalities hold
\[
\|X\|_* = \min_{U \in \mathbb{R}^{m \times d}, V \in \mathbb{R}^{n \times d}, U^T V = X} \frac{1}{2} (\|U\|_F^2 + \|V\|_F^2)
\]
\[
= \min_{U, V : X = U^T V} \|U\|_F \|V\|_F. \tag{4}
\]

The bilinear spectral penalty in the first equality of (4) has been widely used in low-rank matrix completion and recovery problems, such as RPCA [15], [49], online RPCA [68], matrix completion [69], and image inpainting [25].

### 3.1 Double Nuclear Norm Penalty

Inspired by the equivalence relation between the nuclear norm and the bilinear spectral penalty, our double nuclear norm (D-N) penalty is defined as follows.

**Definition 1.** For any matrix $X \in \mathbb{R}^{m \times n}$ of rank at most $r \leq d$, we decompose it into two factor matrices $U \in \mathbb{R}^{m \times d}$ and $V \in \mathbb{R}^{n \times d}$ such that $X = U^T V$. Then the double nuclear norm penalty of $X$ is defined as
\[
\|X\|_{D-N} = \min_{U, V : X = U^T V} \frac{1}{4} (\|U\|_* + \|V\|_*). \tag{5}
\]

Different from the definition in [34], [70], i.e., $\min_{U, V : X = U^T V} \|U\|_* \|V\|_*$ which cannot be used directly to solve practical problems, Definition 1 can be directly used in practical low-rank matrix completion and recovery problems, e.g., RPCA and image recovery. Analogous to the well-known Schatten-$q$ quasi-norm [31], [32], [33], the double nuclear norm penalty is also a quasi-norm, and their relationship is stated in the following theorem.

**Theorem 1.** The double nuclear norm penalty $\| \cdot \|_{D-N}$ is a quasi-norm, and also the Schatten-1/2 quasi-norm, i.e.,
\[
\|X\|_{D-N} = \|X\|_{S_{1/2}}. \tag{6}
\]

To prove Theorem 1, we first give the following lemma, which is mainly used to extend the well-known trace inequality of John von Neumann [71], [72].

**Lemma 2.** Let $X \in \mathbb{R}^{n \times n}$ be a symmetric positive semi-definite (PSD) matrix and its full SVD be $X = U \Sigma U^T$, with $\Sigma = \text{diag}(\lambda_1, \ldots, \lambda_n)$. Suppose $Y$ is a diagonal matrix (i.e., $Y = \text{diag}(\tau_1, \ldots, \tau_n)$), and if $\lambda_1 \geq \cdots \geq \lambda_n \geq 0$ and $0 \leq \tau_1 \leq \cdots \leq \tau_n$, then
\[
\text{Tr}(X^T Y) \geq \sum_{i=1}^n \lambda_i \tau_i. \tag{7}
\]

Lemma 2 can be seen as a special case of the well-known von Neumann’s trace inequality, and its proof is provided in the Supplementary Materials, which can be found on the Computer Society Digital Library at http://doi.ieeecomputersociety.org/10.1109/TPAMI.2017.2748590.

**Lemma 3.** For any matrix $X = UV^T \in \mathbb{R}^{m \times n}, U \in \mathbb{R}^{m \times d}$ and $V \in \mathbb{R}^{n \times d}$, the following inequality holds
\[
\frac{1}{2} (\|U\|_* + \|V\|_*) \geq \|X\|_{S_{1/2}}. \tag{8}
\]

**Proof.** Let $U = L_U \Sigma_U L_U^T$ and $V = L_V \Sigma_V L_V^T$ be the thin SVDs of $U$ and $V$, where $L_U \in \mathbb{R}^{m \times d}, L_V \in \mathbb{R}^{n \times d}$, and $R_U, \Sigma_U, R_V, \Sigma_V \in \mathbb{R}^{d \times d}$. Let $X = L_X \Sigma_X L_X^T$, where the columns of $L_X \in \mathbb{R}^{m \times d}$ and $R_X \in \mathbb{R}^{n \times d}$ are the left and right singular vectors associated with the top $d$ singular values of $X$ with rank at most $r \ (r \leq d)$, and $\Sigma_X = \text{diag}(\sigma_1(X), \ldots, \sigma_r(X), 0, \ldots, 0) \in \mathbb{R}^{d \times d}$.

Suppose $W_1 = L_X \Sigma_U L_V^T, W_2 = L_X \Sigma_U \Sigma_V L_V^T$, and $W_3 = L_X \Sigma_X L_X^T$, we first construct the following PSD matrices $M_1 \in \mathbb{R}^{2m \times 2m}$ and $S_1 \in \mathbb{R}^{2m \times 2m}$
\[
M_1 = \begin{bmatrix} -L_X \Sigma_U^2 & \Sigma_U L_V \Sigma_V L_X^T \\ L_X \Sigma_X \Sigma_V \end{bmatrix}, \quad S_1 = \begin{bmatrix} I_n & L_U \Sigma_U^2 L_U^T \\ L_U \Sigma_U \Sigma_V & L_U \Sigma_U \Sigma_V L_U^T \\ L_U \Sigma_U \Sigma_V L_U^T & L_U \Sigma_U \Sigma_V \end{bmatrix} \tag{9}
\]

Because the trace of the product of two PSD matrices is always non-negative (see the proof of Lemma 6 in [73]), we have
\[
\text{Tr} \left( \begin{bmatrix} I_n & L_U \Sigma_U^2 L_U^T \\ L_U \Sigma_U \Sigma_V & L_U \Sigma_U \Sigma_V L_U^T \\ L_U \Sigma_U \Sigma_V L_U^T & L_U \Sigma_U \Sigma_V \end{bmatrix} \right) \geq 0.
\]

By further simplifying the above expression, we obtain
\[
\text{Tr}(W_1) - 2 \text{Tr}(L_U \Sigma_U^{-1} L_U^T W_2^T) + \text{Tr}(L_U \Sigma_U^{-1} L_U^T W_3) \geq 0. \tag{10}
\]

Recalling $X = UV^T$ and $L_X \Sigma_X L_X^T = L_U \Sigma_U^2 L_U^T R_U \Sigma_U L_U^T$, thus $L_U^T L_X \Sigma_X = L_U \Sigma_U^2 R_U \Sigma_U L_U^T R_U$. Due to the orthonormality of the columns of $L_U, R_U, L_V, R_V, L_X$ and $R_X$, using the well-known trace inequality [71], [72], we obtain
\[
\text{Tr}(L_U \Sigma_U^{-1} L_U^T W_3) = \text{Tr}(L_U \Sigma_U^{-1} L_U^T L_X \Sigma_X L_X^T) = \text{Tr}(L_U \Sigma_U^{-1} \Sigma_U^2 R_U \Sigma_U L_U^T R_U \Sigma_U L_U^T L_X \Sigma_X L_X^T) \leq \text{Tr}(S_X) = \|X\|_*, \tag{11}
\]

Using Lemma 2, we have
\[
\text{Tr}(L_U \Sigma_U^{-2} L_U^T W_2^T) = \text{Tr}(L_U \Sigma_U^{-2} L_U^T L_X \Sigma_X L_X^T) = \text{Tr}(\Sigma_X^{-1} L_U^T L_X \Sigma_X L_X^T) = \text{Tr}(\Sigma_X^{-1} L_U^T L_X \Sigma_X L_X^T) \geq \text{Tr}(X) = \|X\|_{S_{1/2}}. \tag{12}
\]

where $O_1 = L_U^T L_X \in \mathbb{R}^{d \times d}$, and it is easy to verify that $O_1 \Sigma_X^2 \Sigma_X^T$ is a symmetric PSD matrix. Using (7), (8), (9) and $\text{Tr}(W_1) = \|U\|_* \|V\|_*$, we have $\|X\|_* \geq \|X\|_{S_{1/2}}$. \hfill $\square$

The detailed proof of Theorem 1 is provided in the Supplementary Materials, available online. According to
Theorem 1, it is easy to verify that the double nuclear norm penalty possesses the following property [34].

**Property 2.** Given a matrix \( X \in \mathbb{R}^{m \times n} \) with \( \text{rank}(X) \leq d \), the following equalities hold

\[
\|X\|_{\mathcal{D}-N} = \min_{U \in \mathbb{R}^{m \times d}, V \in \mathbb{R}^{n \times d}, X=UV^T} \left( \frac{(\|U\|_F + \|V\|_F)^2}{2} \right)
= \min_{U, V : X=UV^T} \|U\|_F \cdot \|V\|_F.
\]

**3.2 Frobenius/Nuclear Norm Penalty**

Inspired by the definitions of the bilinear spectral and double nuclear norm penalties mentioned above, we define a Frobenius/nuclear hybrid norm (F-N) penalty as follows.

**Definition 2.** For any matrix \( X \in \mathbb{R}^{m \times n} \) of rank at most \( r \leq d \), we decompose it into two factor matrices \( U \in \mathbb{R}^{m \times d} \) and \( V \in \mathbb{R}^{n \times d} \) such that \( X = UV^T \). Then the Frobenius/nuclear hybrid norm penalty of \( X \) is defined as

\[
\|X\|_{F-N} = \min_{U, V : X=UV^T} \left( (\|U\|_F^2 + 2\|V\|_F^2)^{3/2} \right).
\]

Different from the definition in [34], i.e., \( \min_{U, V : X=UV^T} \|U\|_F \cdot \|V\|_F \), Definition 2 can also be directly used in practical problems. Analogous to the double nuclear norm penalty, the Frobenius/nuclear hybrid norm penalty is also a quasi-norm, as stated in the following theorem.

**Theorem 2.** The Frobenius/nuclear hybrid norm penalty, \( \|X\|_{F-N} \), is a quasi-norm, and is also the Schatten-2/3 quasi-norm, i.e.,

\[
\|X\|_{F-N} = \|X\|_{S_{2/3}}.
\]

To prove Theorem 2, we first give the following lemma.

**Lemma 4.** For any matrix \( X = UV^T \in \mathbb{R}^{m \times n} \), \( U \in \mathbb{R}^{m \times d} \) and \( V \in \mathbb{R}^{n \times d} \), the following inequality holds

\[
\frac{1}{3} \left( \|U\|_F^2 + 2\|V\|_F^2 \right) \geq \|X\|_{S_{2/3}}^{2/3}.
\]

**Proof.** To prove this lemma, we use the same notations as in the proof of Lemma 3, e.g., \( X = L_X \Sigma_X R_X^T \), \( U = L_U \Sigma_U R_U^T \) and \( V = L_V \Sigma_V R_V^T \) denote the thin SVDs of \( U \) and \( V \), respectively. Suppose \( \mathcal{W}_1 = R_X \Sigma_X R_X^T \), \( \mathcal{W}_2 = R_X \Sigma_X R_X^T \), and \( \mathcal{W}_3 = R_X \Sigma_X R_X^T \). We first construct the following PSD matrices \( \mathcal{M}_2 \in \mathbb{R}^{2m \times 2m} \) and \( S_2 \in \mathbb{R}^{2m \times 2m} \)

\[
\mathcal{M}_2 = \begin{bmatrix}
-R_X \Sigma_X^2 & [\Sigma_X^2 R_X^T \Sigma_X^2] \\
R_X \Sigma_X^2 & [\Sigma_X^2 R_X^T \Sigma_X^2]
\end{bmatrix}
\begin{bmatrix}
\mathcal{W}_1 & -\mathcal{W}_2 \\
-\mathcal{W}_2 & \mathcal{W}_3
\end{bmatrix} \succeq 0,
\]

\[
S_2 = \begin{bmatrix}
I_n & L_Y \Sigma_V^{-1} L_Y^T \\
L_Y \Sigma_V^{-1} L_Y^T & I_n
\end{bmatrix}
\begin{bmatrix}
I_n & L_Y \Sigma_V^{-1} L_Y^T \\
L_Y \Sigma_V^{-1} L_Y^T & I_n
\end{bmatrix} \succeq 0.
\]

Similar to Lemma 3, we have the following inequality:

\[
\text{Tr} \left( \begin{bmatrix}
I_n & L_Y \Sigma_V^{-1} L_Y^T \\
L_Y \Sigma_V^{-1} L_Y^T & I_n
\end{bmatrix} \begin{bmatrix}
\mathcal{W}_1 & -\mathcal{W}_2 \\
-\mathcal{W}_2 & \mathcal{W}_3
\end{bmatrix} \right) \geq 0.
\]

By further simplifying the above expression, we also obtain

\[
\text{Tr}(\mathcal{W}_1) - 2\text{Tr}(L_Y \Sigma_V^{-1} L_Y^T \mathcal{W}_2^T) + \text{Tr}(L_Y \Sigma_V^{-1} L_Y^T \mathcal{W}_3) \geq 0. \tag{12}
\]

Since \( L_X \Sigma_X R_X^T = L_U \Sigma_U R_U^T L_Y \Sigma_V L_Y^T L_X \Sigma_X = (L_X^T L_U \Sigma_U L_Y^T R_Y \Sigma_V L_Y^T L_X \Sigma_X)^T \), due to the orthonormality of the columns of \( L_U, R_U, L_V, R_V, L_X \) and \( R_X \), and using the von Neumann’s trace inequality [71, 72], we have

\[
\text{Tr}(L_Y \Sigma_V^{-1} L_Y^T \mathcal{W}_3) = \text{Tr}(L_Y \Sigma_V^{-1} L_Y^T R_Y \Sigma_V X \Sigma_X^2 R_X^T) = \text{Tr}(L_Y \Sigma_V^{-1} L_Y^T R_Y \Sigma_V L_Y^T L_X \Sigma_X^2 R_X^T) \leq \text{Tr}(\Sigma_X^2 \Sigma_X^2) \leq \frac{1}{2} (\|U\|_F^2 + \|X\|_{S_{2/3}}^2).
\]

By Lemma 2, we also have

\[
\text{Tr}(L_Y \Sigma_V^{-1} L_Y^T \mathcal{W}_2^T) = \text{Tr}(L_Y \Sigma_V^{-1} L_Y^T R_Y \Sigma_V \Sigma_X \Sigma_X^2 R_X^T) = \text{Tr}(L_Y \Sigma_V^{-1} L_Y^T R_Y \Sigma_V \Sigma_X \Sigma_X^2 R_X^T),
\]

\[
\geq \text{Tr}(\Sigma_X^2 \Sigma_X^2) = \text{Tr}(\Sigma_X^2) = \|X\|_{S_{2/3}}^2.
\]

where \( O_2 = L_Y^T R_X \in \mathbb{R}^{d \times d} \), and it is easy to verify that \( O_2 \Sigma_X^2 \Sigma_X^2 \) is a symmetric PSD matrix. Using (12), (13), (14), and \( \text{Tr}(\mathcal{W}_1) = \|V\|_F \), then we have \( \|U\|_F^2 + 2\|V\|_F^2 \geq 3\|X\|_{S_{2/3}}^2 \).

According to Theorem 2 (see the Supplementary Materials, available online, for its detailed proof), it is easy to verify that the Frobenius/nuclear hybrid norm penalty possesses the following property [34].

**Property 3.** For any matrix \( X \in \mathbb{R}^{m \times n} \) with \( \text{rank}(X) = r \leq d \), the following equalities hold

\[
\|X\|_{F-N} = \min_{U \in \mathbb{R}^{m \times d}, V \in \mathbb{R}^{n \times d}, X=UV^T} \left( \frac{(\|U\|_F^2 + 2\|V\|_F^2)^{3/2}}{3} \right)
= \min_{U, V : X=UV^T} \|U\|_F \cdot \|V\|_F.
\]

Similar to the relationship between the Frobenius norm and nuclear norm, i.e., \( \|X\|_F \leq \|X\|_\cdot \leq \|X\|_{F-N} \leq \|X\|_F \) [26], the bounds hold for between both the double nuclear norm and Frobenius/nuclear hybrid norm penalties and the nuclear norm, as stated in the following property.

**Property 4.** For any matrix \( X \in \mathbb{R}^{m \times n} \), the following inequalities hold

\[
\|X\|_{S_{2/3}} \leq \|X\|_{F-N} \leq \|X\|_{D-N} \leq \|X\|_x.
\]
The proof of Property 4 is similar to that in [34]. Moreover, both the double nuclear norm and Frobenius/nuclear hybrid norm penalties naturally satisfy many properties of quasi-norms, e.g., the unitary-invariant property. Obviously, we can find that Property 4 in turn implies that any low F-N or D-N penalty is also a low nuclear norm approximation.

3.3 Problem Formulations

Without loss of generality, we can assume that the unknown entries of $D$ are set to zero (i.e., $P_{D}(D) = 0$), and $S_{W}$ may be any values (i.e., $S_{W} \in \mathbb{R}^{m \times d}$) such that $P_{D}(L + S) = P_{D}(D)$. Thus, the constraint with the projection operator $P_{N}$ in (2) is considered instead of just $L + S = D$ as in [42]. Together with hyper-Laplacian priors of sparse components, we use $||L||_{2,\infty}$ and $||L||_{2,\infty}$, defined above to replace $||L||_{2,\infty}$ in (2), and present the following double nuclear norm and Frobenius/nuclear hybrid norm penalized RPCA models:

$$\begin{align*}
\min_{U,V,S} & \quad \frac{\lambda}{2} (||U||_{*} + ||V||_{*}) + ||P_{N}(S)||_{1/2}^{1/2}, \\
\text{s.t.} & \quad UV^{T} = L, L + S = D
\end{align*}$$

(15)

$$\begin{align*}
\min_{U,V,L,S} & \quad \frac{\lambda}{3} (||U||_{F}^{2} + 2||V||_{*}) + ||P_{N}(S)||_{2/3}^{2/3}, \\
\text{s.t.} & \quad UV^{T} = L, L + S = D
\end{align*}$$

(16)

From the two proposed models (15) and (16), one can easily see that the norm of each bilinear factor matrix is convex, and they are much more tractable and scalable optimization problems than the original Schatten quasi-norm minimization problem as in (2).

4 Optimization Algorithms

To efficiently solve both our challenging problems (15) and (16), we need to introduce the auxiliary variables $\hat{U}$ and $\hat{V}$, or only $\hat{V}$ to split the interdependent terms such that they can be solved independently. Thus, we can reformulate Problems (15) and (16) into the following equivalent forms

$$\begin{align*}
\min_{U,V,L,S} & \quad \frac{\lambda}{2} (||\hat{U}||_{*} + ||\hat{V}||_{*}) + ||P_{N}(S)||_{1/2}^{1/2}, \\
\text{s.t.} & \quad \hat{U} = U, \hat{V} = V, UV^{T} = L, L + S = D
\end{align*}$$

(17)

$$\begin{align*}
\min_{U,V,L,S} & \quad \frac{\lambda}{3} (||U||_{F}^{2} + 2||V||_{*}) + ||P_{N}(S)||_{2/3}^{2/3}, \\
\text{s.t.} & \quad \hat{V} = V, UV^{T} = L, L + S = D
\end{align*}$$

(18)

4.1 Solving (17) via ADMM

Inspired by recent progress on alternating direction methods [44], [58], we mainly propose an efficient algorithm based on the alternating direction method of multipliers [58] (ADMM, also known as the inexact ALM [44]) to solve the more complex problem (17), whose augmented Lagrangian function is given by

$$\begin{align*}
\min_{U,V,L,S} & \quad \frac{\lambda}{2} (||\hat{U}||_{*} + ||\hat{V}||_{*}) + ||P_{N}(S)||_{1/2}^{1/2} + (Y_{1}, \hat{U} - U) + (Y_{2}, \hat{V} - V) + (Y_{3}, UV^{T} - L) + (Y_{4}, L + S - D) \\
& \quad + \frac{\mu}{2} (||\hat{U} - U||_{F}^{2} + ||\hat{V} - V||_{F}^{2} + ||UV^{T} - L||_{F}^{2} + ||L + S - D||_{F}^{2})
\end{align*}$$

where $\mu > 0$ is the penalty parameter, $<.,.>$ represents the inner product operator, and $Y_{1}, Y_{2} \in \mathbb{R}^{m \times d}, Y_{3} \in \mathbb{R}^{m \times d}$ and $Y_{4} \in \mathbb{R}^{m \times n}$ are Lagrange multipliers.

4.1.1 Updating $\hat{U}_{k+1}$ and $V_{k+1}$

To update $U_{k+1}$ and $V_{k+1}$, we consider the following optimization problems

$$\begin{align*}
\min_{U} & \quad \frac{\lambda}{2} (||\hat{U}||_{*} + ||\hat{V}||_{*}) + ||P_{N}(S)||_{1/2}^{1/2} + ||UV^{T} - L||_{F}^{2} + ||L + S - D||_{F}^{2}\\
& \quad + \frac{\mu}{2} (||\hat{U} - U||_{F}^{2} + ||\hat{V} - V||_{F}^{2} + ||UV^{T} - L||_{F}^{2} + ||L + S - D||_{F}^{2})
\end{align*}$$

(19)

$$\min_{V} \quad \frac{\mu}{2} (||\hat{U} - U||_{F}^{2} + ||\hat{V} - V||_{F}^{2} + ||UV^{T} - L||_{F}^{2} + ||L + S - D||_{F}^{2})$$

(20)

Both (19) and (20) are least squares problems, and their optimal solutions are given by

$$U_{k+1} = (\hat{U} + \mu_{k}^{-1}Y_{1}^{k}) + M_{k}V_{k}) (I_{d} + VTV_{k}^{-1})$$

(21)

$$V_{k+1} = (\hat{V} + \mu_{k}^{-1}Y_{2}^{k}) + M_{k}^{T}U_{k+1}) (I_{d} + U_{k+1}TV_{k+1})$$

(22)

where $M_{k} = L - \mu_{k}^{-1}Y_{3}^{k}$, and $I_{d}$ denotes an identity matrix of size $d \times d$.

Algorithm 1. ADMM for Solving (S+L)$_{1/2}$ Problem (17)

Input: $P_{D}(D) \in \mathbb{R}^{m \times n}$, the given rank $d$, and $\lambda$.

Initialize: $\mu_{0}, \rho > 1, k = 0$, and $\epsilon$.

1: while not converged do
2: \hspace{1em} while not converged do
3: \hspace{2em} Update $U_{k+1}$ and $V_{k+1}$ by (21) and (22).
4: \hspace{2em} Compute $\hat{U}_{k+1}$ and $\hat{V}_{k+1}$ via the SVT operator [23].
5: \hspace{1em} Update $L_{k+1}$ and $S_{k+1}$ by (26) and (29).
6: \hspace{1em} end while// Inner loop
7: Update the multipliers by
8: \hspace{1em} $Y_{1}^{k+1} = Y_{1}^{k} + \mu_{k}(U_{k+1} - U_{k+1})$
9: \hspace{1em} $Y_{2}^{k+1} = Y_{2}^{k} + \mu_{k}(\hat{V}_{k+1} - V_{k})$
10: \hspace{1em} $Y_{3}^{k+1} = Y_{3}^{k} + \mu_{k}(L_{k+1} - L_{k})$
11: \hspace{1em} $Y_{4}^{k+1} = Y_{4}^{k} + \mu_{k}(S_{k+1} - S_{k})$
12: \hspace{1em} $\mu_{k+1} = \mu_{k}$
13: \hspace{1em} $k \leftarrow k + 1$
14: \hspace{1em} end while// Outer loop

Output $U_{k+1}$ and $V_{k+1}$.

4.1.2 Updating $\hat{U}_{k+1}$ and $\hat{V}_{k+1}$

To solve $\hat{U}_{k+1}$ and $\hat{V}_{k+1}$, we fix the other variables and solve the following optimization problems

$$\min_{\hat{U}} \quad \frac{\lambda}{2} (||\hat{U}||_{*} + \mu_{k}^{-1}||Y_{1}^{k}/\mu_{k}||_{F}^{2})$$

(23)

$$\min_{\hat{V}} \quad \frac{\lambda}{2} (||\hat{V}||_{*} + \mu_{k}^{-1}||Y_{2}^{k}/\mu_{k}||_{F}^{2})$$

(24)

Both (23) and (24) are nuclear norm regularized least squares problems, and their closed-form solutions can be given by the so-called SVT operator [23], respectively.
4.1.3 Updating \( L_{k+1} \)

To update \( L_{k+1} \), we can obtain the following optimization problem

\[
\min_L \| U_{k+1} V_{k+1}^T - L + \mu_k Y_k \|_F^2 + \| L + S_k - D + \mu_k^{-1} Y_k \|_F^2. \tag{25}
\]

Since (25) is a least squares problem, and thus its closed-form solution is given by

\[
L_{k+1} = \frac{1}{2} (U_{k+1} V_{k+1}^T + \mu_k^{-1} Y_k - S_k + D - \mu_k^{-1} Y_k). \tag{26}
\]

4.1.4 Updating \( S_{k+1} \)

By keeping all other variables fixed, \( S_{k+1} \) can be updated by solving the following problem

\[
\min_{S} \| P_{\Omega} (S) \|_{\ell_2/3}^{1/2} + \frac{\mu_k}{2} (S + L_{k+1} - D + \mu_k^{-1} Y_k). \tag{27}
\]

Generally, the \( \ell_p \)-norm (\( 0 < p < 1 \)) leads to a non-convex, non-smooth, and non-Lipschitz optimization problem [39]. Fortunately, we can efficiently solve (27) by introducing the following half-thresholding operator [21].

**Proposition 1.** For any matrix \( A \in \mathbb{R}^{m \times n} \), and \( X^* \in \mathbb{R}^{m \times n} \) is an \( \ell_1/2 \)-quasi-norm solution of the following minimization

\[
\min_X \| X - A \|_F^2 + \gamma \| X \|_{\ell_1/2}, \tag{28}
\]

then the solution \( X^* \) can be given by \( X^* = H_{\gamma}(A) \), where the half-thresholding operator \( H_{\gamma}(\cdot) \) is defined as

\[
H_{\gamma}(a_{ij}) = \begin{cases} 
\frac{2}{\gamma} a_{ij} \left[ 1 + \cos \left( \frac{2\pi - 2c_{ij}(a_{ij})}{3} \right) \right], & |a_{ij}| > \frac{2\sqrt{3}\gamma}{3}, \\
0, & \text{otherwise},
\end{cases}
\]

where \( c_{ij}(a_{ij}) = \arccosh(\sqrt{\gamma}) (|a_{ij}|/3)^{3/2} \).

Before giving the proof of Proposition 1, we first give the following lemma [21].

**Lemma 5.** Let \( y \in \mathbb{R}^{n \times 1} \) be a given vector, and \( \tau > 0 \). Suppose that \( x^* \in \mathbb{R}^{n \times 1} \) is a solution of the following problem,

\[
\min_{x} \| B x - y \|_2^2 + \tau \| x \|_{\ell_1/2}^2.
\]

Then for any real parameter \( \mu \in (0, \infty) \), \( x^* \) can be expressed as \( x^* = H_{\mu}(\psi_{\mu}(x^*)) \), where \( \psi_{\mu}(x^*) = x^* + \mu B^T (y - B x^*) \).

**Proof.** The formulation (28) can be reformulated as the following equivalent form

\[
\min_{vec(X)} \| vec(X) - vec(A) \|_F^2 + \gamma \| vec(X) \|_{\ell_1/2}.
\]

Let \( B = I_{m \times n} \mu = 1 \), and using Lemma 5, the closed-form solution of (28) is given by \( vec(X^*) = H_{\gamma}(vec(A)) \). \( \square \)

Using Proposition 1, the closed-form solution of (27) is

\[
S_{k+1} = P_{\Omega} (H_{\ell_2/3}(D - L_{k+1} - \mu_k^{-1} Y_k)) + P_{\Omega} (D - L_{k+1} - \mu_k^{-1} Y_k)
\]

where \( P_{\Omega} \) is the complementary operator of \( P_{\Omega} \). Alternatively, Zuo et al. [22] proposed a generalized shrinkage-thresholding operator to iteratively solve \( \ell_p \)-norm minimization with arbitrary \( p \) values, i.e., \( 0 \leq p < 1 \), and achieve a higher efficiency.

Based on the description above, we develop an efficient ADMM algorithm to solve the double nuclear norm penalized problem (17), as outlined in Algorithm 1. To further accelerate the convergence of the algorithm, the penalty parameter \( \mu \), as well as \( \rho \), are adaptively updated by the strategy as in [44]. The varying \( \mu \), together with shrinkage-thresholding operators such as the SVT operator, sometimes play the role of adaptive selection on the rank of matrices or the number of non-zeros elements. We found that updating \( \{ U_k, V_k \} \), \( \{ \hat{U}_k, \hat{V}_k \} \), \( L_k \) and \( S_k \) just once in the inner loop is sufficient to generate a satisfying accurate solution of (17), so also called inexact ALM, which is used for computational efficiency. In addition, we initialize all the elements of the Lagrange multipliers \( Y_1, Y_2 \) and \( Y_3 \) to 0, while all elements in \( Y_4 \) are initialized by the same way as in [44].

4.2 Solving (18) via ADMM

Similar to Algorithm 1, we also propose an efficient ADMM algorithm to solve (18) (i.e., Algorithm 2), and provide the details in the Supplementary Materials, available online. Since the update schemes of \( U_k, V_k, \hat{U}_k, \hat{V}_k \) and \( L_k \) are very similar to that of Algorithm 1, we discuss their major differences below.

By keeping all other variables fixed, \( S_{k+1} \) can be updated by solving the following problem

\[
\min_{S} \| P_{\Omega} (S) \|_{\ell_2/3}^{1/2} + \frac{\mu_k}{2} (S + L_{k+1} - D + \mu_k^{-1} Y_k). \tag{29}
\]

Inspired by [10], [22], [74], we introduce the following two-thirds-thresholding operator to efficiently solve (30).

**Proposition 2.** For any matrix \( C \in \mathbb{R}^{m \times n} \), and \( X^* \in \mathbb{R}^{m \times n} \) is an \( \ell_2/3 \)-quasi-norm solution of the following minimization

\[
\min_X \| X - C \|_F^2 + \gamma \| X \|_{\ell_2/3}, \tag{31}
\]

then the solution \( X^* \) can be given by \( X^* = T_{\gamma}(C) \), where the two-thirds-thresholding operator \( T_{\gamma}(\cdot) \) is defined as

\[
T_{\gamma}(c_{ij}) = \begin{cases} 
\text{sgn}(c_{ij}) \left( \psi_{\gamma}(c_{ij}) + \frac{27}{8} \frac{\sqrt{27}}{\sqrt[3]{3}} \sqrt{\cosh(arccosh(\frac{27\gamma}{16}) \gamma^{-3/2})} \right)^{3}, & |c_{ij}| > \frac{2\sqrt{3}\gamma}{3}, \\
0, & \text{otherwise},
\end{cases}
\]

where \( \psi_{\gamma}(c_{ij}) = \frac{2\sqrt{3}}{3} \sqrt{\gamma} \cosh(arccosh(\frac{27\gamma}{16})) \). \( \text{sgn}(\cdot) \) is the sign function.

Before giving the proof of Proposition 2, we first give the following lemma [22], [74].

**Lemma 6.** Let \( y \in \mathbb{R} \) be a given real number, and \( \tau > 0 \). Suppose that \( x^* \in \mathbb{R} \) is a solution of the following problem,

\[
\min_{x} x^2 - 2xy + \tau |x|^{2/3}. \tag{32}
\]

Then \( x^* \) has the following closed-form thresholding formula

\[
x^* = \begin{cases} 
\frac{\text{sgn}(y) \left( \sqrt{27/8} \sqrt{\frac{\text{sgn}(y)}{\sqrt{3}}} \right)^{3}, & |y| > \frac{2\sqrt{3}\gamma}{3}, \\
0, & \text{otherwise},
\end{cases}
\]

**Proof.** It is clear that the operator in Lemma 6 can be extended to vectors and matrices by applying it element-wise. Using Lemma 6, the closed-form thresholding formula of (31) is given by \( X^* = T_{\gamma}(C) \). \( \square \)
By Proposition 2, the closed-form solution of (30) is

\[
S_{k+1} = \mathcal{P}_\Omega(T_{2/\mu_k}^k(D - L_{k+1} - \mu_k^{-1}Y_3^k)) \\
+ \mathcal{P}_\Omega^U(D - L_{k+1} - \mu_k^{-1}Y_4^k).
\]

(33)

5 ALGORITHM ANALYSIS

We mainly analyze the convergence property of Algorithm 1. Naturally, the convergence of Algorithm 2 can also be guaranteed in a similar way. Moreover, we also analyze their per-iteration complexity.

5.1 Convergence Analysis

Before analyzing the convergence of Algorithm 1, we first introduce the definition of the critical points (or stationary points) of a non-convex function given in [75].

Definition 3. Given a function \( f : \mathbb{R}^n \to (-\infty, +\infty] \), we denote the domain of \( f \) by \( \text{dom} f \), i.e., \( \text{dom} f := \{ x \in \mathbb{R}^n : f(x) \leq +\infty \} \). A function \( f \) is said to be proper if \( \text{dom} f \neq \emptyset \); lower semi-continuous at the point \( x_0 \) if \( \lim_{x \to x_0} \inf f(x) \geq f(x_0) \). If \( f \) is lower semicontinuous at every point of its domain, then it is called a lower semicontinuous function.

Definition 4. Let a non-convex function \( f : \mathbb{R}^n \to (-\infty, +\infty] \) be a proper and lower semi-continuous function. \( x \) is a critical point of \( f \) if \( 0 \in \partial f(x) \), where \( \partial f(x) \) is the limiting sub-differential of \( f \) at \( x \). \( \partial f(x) = \{ u \in \mathbb{R}^n : \exists x_k \to x, f(x_k) \to f(x) \text{ and } u^k \to \partial f(x_k) \to u \text{ as } k \to \infty \} \), and \( \partial f(x) \) is the Fréchet sub-differential of \( f \) at \( x \) (see [75] for more details).

As stated in [45], [76], the general convergence property of the ADMM for non-convex problems has not been answered yet, especially for multi-block cases [76], [77]. For such challenging problems (15) and (16), although it is difficult to guarantee the convergence to a local minimum, our empirical convergence tests showed that our algorithms have strong convergence behavior (see the Supplementary Materials, available online, for details). Besides the empirical behavior, we also provide the convergence property for Algorithm 1 in the following theorem.

Theorem 3. Let \( \{ (U_k, V_k, \tilde{U}_k, \tilde{V}_k, L_k, S_k, \{ Y_{ik}^k \}) \} \) be the sequence generated by Algorithm 1. Suppose that the sequence \( \{ Y_{ik}^k \} \) is bounded, and \( \mu_k \) is non-decreasing and \( \sum_{k=0}^{\infty} (\mu_{k+1}/\mu_k^{3/2}) < \infty \), then

(I) \( \{ (U_k, V_k) \}, \{ (\tilde{U}_k, \tilde{V}_k) \}, \{ L_k \} \) and \( \{ S_k \} \) are all Cauchy sequences;

(II) Any accumulation point of the sequence \( \{ (U_k, V_k, \tilde{U}_k, \tilde{V}_k, L_k, S_k) \} \) satisfies the Karush-Kuhn-Tucker (KKT) conditions for Problem (17).

The proof of Theorem 3 can be found in the Supplementary Materials, available online. Theorem 3 shows that under mild conditions, any accumulation point (or limit point) of the sequence generated by Algorithm 1 is a critical point of the Lagrangian function \( \mathcal{L}_\rho \), i.e., \( (U_v, V_v, \tilde{U}_v, \tilde{V}_v, L_v, S_v, \{ Y_{ik}^v \}) \), which satisfies the first-order optimality conditions (i.e., the KKT conditions) of (17):

\[
0 \in \frac{1}{\rho} \partial \| \tilde{U}_v \|_1 + Y_{1v}^v, \quad 0 \in \frac{1}{\rho} \partial \| \tilde{V}_v \|_1 + Y_{2v}^v, \quad 0 \in \partial \Phi(S_v) + \mathcal{P}_\Omega(Y_{3v}^v), \quad \mathcal{P}_\Omega^U(Y_{4v}^v) = 0, \quad L_v = U_v V_v^T, \quad \tilde{U}_v = \tilde{V}_v, \quad \tilde{V}_v = V_v, \quad L_v + S_v = D_v, \quad \text{where } \Phi(S_v) := \| \mathcal{P}_\Omega(S_v) \|_1^{1/2}.
\]

Similarly, the convergence of Algorithm 2 can also be guaranteed.

Theorem 3 is established for the proposed ADMM algorithm, which has only a single iteration in the inner loop. When the inner-loop iterations of Algorithm 1 iterate until convergence, it may lead to a simpler proof. We leave further theoretical analysis of convergence as future work.

Theorem 3 also shows that our ADMM algorithms have much weaker convergence conditions than the ones in [15], [45], e.g., the sequence of only one Lagrange multiplier is required to be bounded for our algorithms, while the ADMM algorithms in [15], [45] require the sequences of all Lagrange multipliers to be bounded.

5.2 Convergence Behavior

According to the KKT conditions of (17) mentioned above, we take the following conditions as the stopping criterion for our algorithms (see details in Supplementary Materials, available online),

\[
\max \left\{ \epsilon_1 / \| D \|_F, \epsilon_2 \right\} < \epsilon,
\]

where \( \epsilon_1 = \max \left\{ \| U_k V_1^k - L_k \|_F, \| L_k + S_k - D \|_F, \| Y_{1k}^k (V_k^k) - (U_k^k)^T \|_F, \| Y_{2k}^k \|_F \right\} \), \( \epsilon_2 = \max \left\{ \| U_k - U_k^k \|_F / \| U_k \|_F, \| V_k - V_k^k \|_F / \| V_k \|_F \right\} \), \( (V_k^k) \) is the pseudo-inverse of \( V_k \), and \( \epsilon \) is the stopping tolerance. In this paper, we set the stopping tolerance to \( \epsilon = 10^{-5} \) for synthetic data and \( \epsilon = 10^{-4} \) for real-world problems. As shown in the Supplementary Materials, available online, the stopping tolerance and relative squared error (RSE) of our methods decrease fast, and they converge within only a small number of iterations (usually within 50 iterations).

5.3 Computational Complexity

The per-iteration cost of existing Schatten quasi-norm minimization methods such as LpSq [31] is dominated by the computation of the thin SVD of an \( m \times n \) matrix with \( m \geq n \), and is \( O(mn^2) \). In contrast, the time complexity of computing SVD for (23) and (24) is \( O(mn^2 + nd^2) \). The dominant cost of each iteration in Algorithm 1 corresponds to the matrix multiplications in the update of \( U, V, L, \) and \( T \), which take \( O(mn^2 + d^2) \). Given that \( d \ll m, n \), the overall complexity of Algorithm 1, as well as Algorithm 2, is thus \( O(mn^2) \), which is the same as the complexity of LMaFit [47], RegL1 [16], ROSL [64], Unifying [49], and factEN [15].

6 EXPERIMENTAL RESULTS

In this section, we evaluate both the effectiveness and efficiency of our methods (i.e., (S+L)1/2 and (S+L)3/2) for solving extensive synthetic and real-world problems. We also compare our methods with several state-of-the-art methods, such as LMaFit3 [47], RegL14 [16], Unifying [49], factEN5 [15], RPCA6 [44], IPSVT2 [45], WNNM6 [46], and LpSq9 [31].

6.1 Rank Estimation

As suggested in [6], [28], the regularization parameter \( \lambda \) of our two methods is generally set to \( \sqrt{\max(m, n)} \). Analogous

4. https://sites.google.com/site/yinquanzheng/
9. https://sites.google.com/site/feipingnie/
to other matrix factorization methods [15], [16], [47], [49], two proposed methods also have another important rank parameter, $d$. To estimate it, we design a simple rank estimation procedure. Since the observed data may be corrupted by noise/outlier and/or missing data, our rank estimation procedure combines two key techniques. First, we efficiently compute the $k$ largest singular values of the input matrix (usually $k = 100$), and then use the basic spectral gap technique for determining the number of clusters [78]. Moreover, the rank estimator for incomplete matrices is exploited to look for an index for which the ratio between two consecutive singular values is minimized, as suggested in [79]. We conduct some experiments on corrupted matrices to test the performance of our rank estimation procedure, as shown in Fig. 3. Note that the input matrices are corrupted by both sparse outliers and Gaussian noise as shown below, where the fraction of sparse outliers varies from 0 to 25 percent, and the noise factor of Gaussian noise is changed from 0 to 0.5. It can be seen that our rank estimation procedure performs well in terms of robustness to noise and outliers.

**6.2 Synthetic Data**

We generated the low-rank matrix $L^* \in \mathbb{R}^{m \times n}$ of rank $r$ as the product $PQ^T$, where $P \in \mathbb{R}^{m \times r}$ and $Q \in \mathbb{R}^{n \times r}$ are independent matrices whose elements are independent and identically distributed (i.i.d.) random variables sampled from standard Gaussian distributions. The sparse matrix $S^* \in \mathbb{R}^{m \times n}$ is generated by the following procedure: its support is chosen uniformly at random and the non-zero entries are i.i.d. random variables sampled uniformly in the interval $[-5, 5]$. The input matrix is $D = L^* + S^* + N$, where the Gaussian noise is $N = nf \times \text{randn}$ and $nf \geq 0$ is the noise factor. For quantitative evaluation, we measured the performance of low-rank component recovery by the RSE, and evaluated the accuracy of outlier detection by the F-measure (abbreviated to F-M) as in [17]. The higher F-M or lower RSE, the better is the quality of the recovered results.

### 6.2.1 Model Comparison

We first compared our methods with RPCA (nuclear norm & $\ell_1$-norm), PSVT (truncated nuclear norm & $\ell_1$-norm), WNMM (weighted nuclear norm & $\ell_1$-norm), LpSq (Schatten $q$-norm & $\ell_p$-norm), and Unifying (bilinear spectral penalty & $\ell_1$-norm), where $p$ and $q$ in LpSq are chosen from the range of $\{0.1, 0.2, \ldots, 1\}$. A phase transition plot uses magnitude to depict how likely a certain kind of low-rank matrices can be recovered by those methods for a range of different matrix ranks and corruption ratios. If the recovered matrix $L$ has a RSE smaller than $10^{-2}$, we consider the estimation of both $L$ and $S$ is regarded as successful. Fig. 4 shows the phase transition results of RPCA, PSVT, WNMM, LpSq, Unifying and both our methods on outlier corrupted matrices of size $200 \times 200$ and $500 \times 500$, where the corruption ratios varied from 0 to 0.5 with increment 0.05, and the true rank $r$ from 5 to 50 with increment 5. Note that the rank parameter of PSVT, Unifying, and both our methods is set to $d = \lfloor 1.25r \rfloor$ as suggested in [34], [47]. The results show that both our methods perform significantly better than the other methods, which justifies the effectiveness of the proposed RPCA models (15) and (16).

To verify the robustness of our methods, the observed matrices are corrupted by both Gaussian noise and outliers, where the noise factor and outlier ratio are set to $nf = 0.5$ and 20 percent. The average results (including RSE, F-M, and running time) of 10 independent runs on corrupted matrices with different sizes are reported in Table 3. Note that the rank parameter $d$ of PSVT, Unifying, and both our methods is computed by our rank estimation procedure. It is clear that both our methods significantly outperform all the other methods in terms of both RSE and F-M in all settings. Those non-convex methods including PSVT, WNMM, LpSq, Unifying, and both our methods consistently perform better than the convex method, RPCA, in terms of both RSE and F-M. Impressively, both our methods are much faster than the other methods, and at least 10 times faster than RPCA, PSVT, WNMM, and LpSq in the case when the size of matrices exceeds $5,000 \times 5,000$. This actually shows that our methods are more scalable,
and have even greater advantage over existing methods for handling large matrices.

We also report the RSE results of both our methods on corrupted matrices of size 500 × 500 and 1,000 × 1,000 with outlier ratio 15 percent, as shown in Fig. 5, where the true ranks of those matrices are 10 and 20, and the noise factor ranges from 0.1 to 0.5. In addition, we provide the best results of two baseline methods, WNNM and Unifying. Note that the parameter \( d \) of Unifying and both our methods is computed via our rank estimation procedure. From the results, we can observe that both our methods are much more robust against Gaussian noise than WNNM and Unifying, and have much greater advantage over them in cases when the noise level is relatively large, e.g., 0.5.

### 6.2.2 Comparisons with Other Methods

Figs. 6a and 6b show the average F-measure and RSE results of different matrix factorization based methods on 1,000 × 1,000 matrices with different outliers ratios, where the noise factor is set to 0.2. For fair comparison, the rank parameter of all these methods is set to \( d = \lfloor 1.25r \rfloor \) as in [34], [47]. In all cases, RegL1 [16], Unifying [49], factEN [15], and both our methods have significantly better performance than LMaFit [47], where the latter has no regularizers. This empirically verifies the importance of low-rank regularizers including our defined bilinear factor matrix norm penalties. Moreover, we report the average RSE results of these matrix factorization based methods with outlier ratio 5 percent and various missing ratios in Figs. 6c and 6d, in which we also present the results of LpSq. One can see that only with a very limited number of observations (e.g., 80 percent missing ratio), both our methods yield much more accurate solutions than the other methods including LpSq, while more observations are available, both LpSq and our methods significantly outperform the other methods in terms of RSE.

Finally, we report the performance of all those methods mentioned above on corrupted matrices of size 1,000 × 1,000 as running time goes by, as shown in Fig. 7. It is clear that both our methods obtain significantly more accurate solutions than the other methods with much shorter running time. Different from all other methods, the performance of LMaFit becomes even worse over time, which may be caused by the intrinsic model without a regularizer. This also empirically verifies the importance of all low-rank regularizers, including our defined bilinear factor matrix norm penalties, for recovering low-rank matrices.

### 6.3 Real-World Applications

In this section, we apply our methods to solve various low-level vision problems, e.g., text removal, moving object detection, and image alignment and inpainting.

We highlight the best results in **bold** and the second best in *italic* for each of three performance metrics. Note that WNNM and LpSq could not yield experimental results on the largest problem within 24 hours.
We first apply our methods to detect some text and remove them from the image used in [70]. The ground-truth image is of size 256 x 256 with rank equal to 10, as shown in Fig. 8a. The input data are generated by setting 5 percent of the randomly selected pixels as missing entries. For fairness, we set the rank parameter of PSVT [45], Unifying [49] and our methods to 20, and the stopping tolerance $\epsilon = 10^{-4}$ for all these algorithms. The text detection and removal results are shown in Fig. 8, where the text detection accuracy (F-M) and the RSE of recovered low-rank component are also reported. The results show that both our methods significantly outperform the other methods not only visually but also quantitatively. The running time of our methods and the Schatten quasi-norm minimization method, LpSq [31], is 1.36, 1.21 and 77.65 sec, respectively, which show that both our methods are more than 50 times faster than LpSq.

We test our methods on real surveillance videos for moving object detection and background subtraction as a RPCA plus matrix completion problem. Background modeling is a crucial task for motion segmentation in surveillance videos. A video sequence satisfies the low-rank and sparse structures, because the background of all the frames is controlled by few factors and hence exhibits low-rank property, and the foreground is detected by identifying spatially localized sparse residuals [6], [17], [40]. We test our methods on real surveillance videos for object detection and background subtraction on five surveillance videos: Bootstrap, Hall, Lobby, Mall and WaterSurface databases.10 The input data are generated by setting 10 percent of the randomly selected pixels of each frame as missing entries, as shown in Fig. 9a.

Figs. 9b, 9c, 9d, 9e, and 9f show the foreground and background separation results on the Bootstrap data set. The one frame with missing data of each sequence (top) and its manual segmentation (bottom) are shown in (a). The results of different algorithms are presented from (b) to (f), respectively. The top panel is the recovered background, and the bottom panel is the segmentation.

sets, as shown in Fig. 10, from which we can observe that both our methods consistently outperform the other methods in terms of F-measure. Moreover, Unifying and our methods are much faster than RegL1. Although factEN is slightly faster than Unifying and our methods, it usually has poorer quality of the results.

### 6.3.3 Image Alignment

We also study the performance of our methods in the application of robust image alignment: Given $n$ images $\{I_1, \ldots, I_n\}$ of an object of interest, the image alignment task aims to align them using a fixed geometric transformation model, such as affine [50]. For this problem, we search for a transformation $\tau = [\tau_1, \ldots, \tau_n]$ and write $D \circ \tau = [\text{vec}(I_1 \circ \tau_1)] \cdots [\text{vec}(I_n \circ \tau_n)] \in \mathbb{R}^{m \times n}$. In order to robustly align the set of linearly correlated images despite sparse outliers, we consider the following double nuclear norm regularized model

$$\min_{U \in \mathbb{S}_+^2, V \in \mathbb{S}_+^2} \lambda_1 \cdot \|U\|_* + \|V\|_* + \|S\|_{1/2}^{1/2}, \text{s.t.}, D \circ \tau = UV^T + S. \quad (34)$$

Alternatively, our Frobenius/nuclear norm penalty can also be used to address the image alignment problem above.

We first test both our methods on the Windows data set (which contains 16 images of a building, taken from various viewpoints by a perspective camera, and with occlusions due to tree branches) used in [50] and report the aligned results of RASL [50], PSVT [45] and our methods in Fig. 11, from which it is clear that, compared with RASL and PSVT, both our methods not only robustly align the images, correctly detect and remove the occlusion, but also achieve much better performance in terms of low-rank components, as shown in Figs. 11d and 11h, which give the close-up views of the red boxes in Figs. 11c and 11g, respectively.

### 6.3.4 Image Inpainting

Finally, we applied the defined D-N and F-N penalties to image inpainting. As shown by Hu et al. [38], the images of natural scenes can be viewed as approximately low rank matrices. Naturally, we consider the following D-N penalty regularized least squares problem

$$\min_{UV^T} \frac{\lambda}{2} \|U\|_* + \|V\|_* + \frac{1}{2} \|P_0(L - D)\|^2_F, \text{s.t.}, L = UV^T. \quad (35)$$

The F-N penalty regularized model and the corresponding ADMM algorithms for solving both models are provided in the Supplementary Materials, available online. We compared our methods with one nuclear norm solver [43], one weighted nuclear norm method [37], [46], two truncated nuclear norm methods [38], [45], and one Schatten-\(q\) quasi-norm method [19]. Since both of the ADMM algorithms in [38], [45] have very similar performance as shown in [45], we only report the results of [38]. For fair comparison, we set the same values to the parameters $d$, $\rho$ and $\mu_0$ for both our methods and [38], [45], e.g., $d = 9$ as in [38].

Fig. 12 shows the 8 test images and some quantitative results (including average PSNR and running time) of all those methods with 85 percent random missing pixels. We also show the inpainting results of different methods for random mask of 80 percent missing pixels in Fig. 13 (see the Supplementary Materials, available online, for more results with different missing ratios and rank parameters). The results show that both our methods consistently produce much better PSNR results than the other methods in all the settings. As analyzed in [34], [70], our D-N and F-N penalties not only lead to two scalable optimization problems, but also require

significantly fewer observations than traditional nuclear norm solvers, e.g., [43]. Moreover, both our methods are much faster than the other methods, in particular, more than 25 times faster than the methods [19], [38], [46].

7 Conclusion and Discussions

In this paper we defined the double nuclear norm and Frobenius/nuclear hybrid norm penalties, which are in essence the Schatten-1/2 and 2/3 quasi-norms, respectively. To take advantage of the hyper-Laplacian priors of sparse noise/outliers and singular values of low-rank components, we proposed two novel tractable bilinear factor matrix norm penalized methods for low-level vision problems. Our experimental results show that both our methods can yield more accurate solutions than original Schatten quasi-norm minimization when the number of observations is very limited, while the solutions obtained by the three methods are almost identical when a sufficient number of observations is observed. The effectiveness and generality of both our methods are demonstrated through extensive experiments on both synthetic data and real-world applications, whose results also show that both our methods perform more robust to outliers and missing ratios than existing methods.

An interesting direction of future work is the theoretical analysis of the properties of both of our bilinear factor matrix norm penalties compared to the nuclear norm and the Schatten quasi-norm. For example, how many observations are sufficient for both our models to reliably recover low-rank matrices, although in our experiments we found that our methods perform much better than existing Schatten quasi-norm methods with a limited number of observations. In addition, we are interested in exploring ways to regularize our models with auxiliary information, such as graph Laplacian [27], [80], [81] and hyper-Laplacian matrix [82], or the elastic-net [15]. We can apply our bilinear factor matrix norm penalties to various structured sparse and low-rank problems [5], [17], [28], [33], e.g., corrupted columns [9] and Hankel matrix for image restoration [25].
